certify that this submission is my original work and that I have adhered to the guidelines specified for this assessment. I understand that any violation of academic integrity rules will result in disciplinary action.

Signature of the Student: K. Kabilan**Instructions**

- This test contains 5 Comparative Analysis questions. Total: 100 Marks.
- When a student answer using comparative analysis should be based on four requirements: time complexity, space complexity advantages & limitations, real-world scenarios and operations.
- No negative marking. Unanswered questions carry zero marks.
- No DTP printouts or electronic devices permitted. They should provide written materials.

| Section / Topic    | Focus                                   | Q Nos | Marks     |
|--------------------|-----------------------------------------|-------|-----------|
| Hashing            | Linear Probing & Separate Chaining      | 1     | 20        |
| Sorting            | Merge Sort & Quick Sort                 | 2     | 20        |
| Hashing            | Quadratic Probing and Double Hashing    | 3     | 20        |
| Sorting Algorithms | Complexity Analysis                     | 4     | 20        |
| Quick Sort         | Recursive and Iterative implementations | 5     | 20        |
| GRAND TOTAL:       |                                         |       | 100 Marks |

### Annexure A – Comparative Analysis

1. Compare Linear Probing and Separate Chaining for collision handling in hashing based on: (20 Marks)
  - a) Clustering effect
  - b) Memory usage
  - c) Performance under high load factor
  - d) Which method is more suitable for large-scale applications and why?
2. Compare quick sort and merge sort for sorting a large linked list of 10 million nodes. Analyze memory requirements (in-place vs. extra space), cache behavior, and time complexity. Which algorithm is preferable for linked lists and why? How does the answer change for arrays? (20 Marks)
3. Compare Quadratic Probing and Double Hashing in terms of: (20 Marks)
  - a) Clustering issues
  - b) Collision resolution efficiency
  - c) Suitability for dense hash tables
4. Compare Best-case and Worst-case time complexity of sorting algorithms based on the following: (20 Marks)
  - a) Practical significance
  - b) Impact on algorithm selection
5. Compare Recursive and Iterative implementations of Quick Sort in terms of: (20 Marks)
  - a) Space complexity (stack usage)
  - b) Ease of implementation
  - c) Risk of stack overflow

### Rubrics for Calculation

| Criteria                                  | Weightage | Level 4 – Exemplary                                                                            | Level 3 – Proficient                             | Level 2 – Developing                             | Level 1 – Beginning                |
|-------------------------------------------|-----------|------------------------------------------------------------------------------------------------|--------------------------------------------------|--------------------------------------------------|------------------------------------|
| Concept Understanding                     | 20        | Demonstrates complete and accurate understanding of all data structures with advanced insights | Shows clear understanding with minor gaps        | Basic understanding; some misconceptions present | Limited or incorrect understanding |
| Comparative Analysis Depth                | 20        | Thorough, multi-dimensional comparison with strong justification and critical evaluation       | Good comparison with relevant factors considered | Limited comparison; lacks depth or justification | Minimal or incorrect comparison    |
| Use of Parameters (Time/Space/Operations) | 30        | All parameters analysed accurately with complexity discussion                                  | Most parameters covered correctly                | Few parameters considered; some inaccuracies     | Parameters missing or incorrect    |
| Critical Thinking                         | 20        | Strong justification of why one structure is better in given contexts                          | Some justification present                       | Limited reasoning                                | No critical reasoning              |
| Clarity                                   | 10        | Exceptionally well-structured, logical flow, clear tables/diagrams                             | Well-organized with minor issues                 | Some organization issues; lacks clarity          | Poor structure and readability     |

| Faculty In-charge                                                                              | Course Coordinator | Program Director |

Course: Data Structures  
Course Code: CSA0306  
Date: 18/02/2026

1) Compare linear probing and separate chaining for collision handling in hashing based on: a) clustering effect b) memory usage c) performance under high load factor d) which method is more suitable for large-scale application

| Factor                   | Linear probing                                 | Separate chaining                                          |
|--------------------------|------------------------------------------------|------------------------------------------------------------|
| Clustering effect        | suffers from                                   | Less clustering                                            |
| Memory usage             | uses less memory because no extra linked lists | uses more memory pointers/nodes                            |
| High load factor         | performance decreases quickly                  | performs better                                            |
| Large-scale applications | Less suitable when Table becomes full          | more suitable because it handles collisions and high load. |

Conclusion: separate chaining is generally preferred for large-scale applications because works efficiently even at higher load factors

2) Compare quick sort and merge sort for sorting a linked list of 10 million nodes. Analyze memory requirements, cache behaviour, and Time complexity.

For a linked list of 10 million nodes.

| Factor             | Quick sort                                        | Merge sort                              |
|--------------------|---------------------------------------------------|-----------------------------------------|
| Time complexity    | Average: $O(n \log n)$ ,<br>worst: $O(n^2)$       | Best / Average / worst<br>$O(n \log n)$ |
| Extra memory       | $O(\log n)$ array stack                           | $O(\log n)$ recursion stack             |
| Linked-list access | Not efficient because partitioning is difficult   | very efficient                          |
| Cache behaviour    | Better for arrays, but not ideal for linked lists | sequential access suits linked lists    |
| Stability          | usually not stable                                | Stable                                  |

Conclusion:

↳ merge sort is preferable for large linked lists because it provides  $O(n \log n)$  Time, requires less extra space, and works efficiently.

↳ For arrays, Quick sort is generally preferable because it is in place, cache-friendly and fast in practice.

Compare Quadratic Probing and Double Hashing in terms of:

- Clustering issues
- Collision resolution efficiency
- suitable for dense hash Tables.

| Factor               | Quadratic Probing                                             | Double Hashing                                 |
|----------------------|---------------------------------------------------------------|------------------------------------------------|
| Clustering           | Reduces primary clustering but can have secondary clustering. | Avoids primary and secondary clustering better |
| Collision resolution | Good                                                          | More efficient                                 |
| Dense hash Tables    | performance decreases at high load.                           | Better for dense Tables.                       |
| Probe sequence       | use quadratic function                                        | uses a secondary hash function.                |

Conclusion: Double Hashing is generally better because it provides a more uniform distribution of probes and works better when the hash Table is highly loaded.

- 4) Compare Best-Case and worst-Case Time Complexity of Sorting algorithm based on a) practical significance  
b) Impact on algorithm.

| Factor                 | Best case                               | worst case                      |
|------------------------|-----------------------------------------|---------------------------------|
| Meaning                | Minimum Time required                   | Maximum Time required           |
| practical significance | shows ideal performance                 | shows possible poor performance |
| Algorithm relation     | useful when input is usually favourable | more important for reliability  |
| Example                | Quick sort: $O(n \log n)$               | Quick sort: $O(n^2)$            |

Conclusion: Best-Case Complexity shows the minimum time an algorithm may take, while worst-Case Complexity shows the maximum time. For large and unpredictable inputs, algorithm with better worst-case performance are generally preferred.

Compare Recursive and Iterative implementation of Quick Sort in terms of:

- space complexity
- Ease of implementation
- Risk of stack overflow answer for these questions.

| Factor                 | Recursive Quick Sort                           | Iterative Quick Sort                       |
|------------------------|------------------------------------------------|--------------------------------------------|
| space complexity       | $O(\log n)$ average stack<br>$O(n)$ worst case | uses an explicit stack                     |
| Ease of Implementation | Easy and simple                                | more complex                               |
| stack overflow         | Higher risk for bad partitions                 | Lower risk because stack can be controlled |
| Code                   | shorter                                        | Longer                                     |

↳ Recursive Quick Sort is easier to implement but may cause stack overflow for large or unbalanced inputs. Iterative Quick Sort avoids this risk by using an explicit stack.

↳ Iterative Quick Sort is safer for large datasets, while recursive Quick Sort is simpler to implement.
